FENNEMA, ROBERT E

ART UNIT

PAPER NUMBER

2183

MAIL DATE

DELIVERY MODE

05/23/2008

PAPER

**Please find below and/or attached an Office communication concerning this application or proceeding.**

The time period for reply, if any, is set in the attached communication.

<b>Office Action Summary</b>	<b>Application No.</b> 10/816,103	<b>Applicant(s)</b> GROCHOWSKI ET AL.	
	<b>Examiner</b> ROBERT E. FENNEMA	<b>Art Unit</b> 2183	

-- The MAILING DATE of this communication appears on the cover sheet with the correspondence address --

### Period for Reply

A SHORTENED STATUTORY PERIOD FOR REPLY IS SET TO EXPIRE 3 MONTH(S) OR THIRTY (30) DAYS, WHICHEVER IS LONGER, FROM THE MAILING DATE OF THIS COMMUNICATION.

- Extensions of time may be available under the provisions of 37 CFR 1.136(a). In no event, however, may a reply be timely filed after SIX (6) MONTHS from the mailing date of this communication.
- If NO period for reply is specified above, the maximum statutory period will apply and will expire SIX (6) MONTHS from the mailing date of this communication.
- Failure to reply within the set or extended period for reply will, by statute, cause the application to become ABANDONED (35 U.S.C. § 133). Any reply received by the Office later than three months after the mailing date of this communication, even if timely filed, may reduce any earned patent term adjustment. See 37 CFR 1.704(b).

### Status

- 1) ☒ Responsive to communication(s) filed on 15 February 2008.
- 2a) ☒ This action is **FINAL**. 2b) ☐ This action is non-final.
- 3) ☐ Since this application is in condition for allowance except for formal matters, prosecution as to the merits is closed in accordance with the practice under *Ex parte Quayle*, 1935 C.D. 11, 453 O.G. 213.

### Disposition of Claims

- 4) ☒ Claim(s) 1-17, 20-28, 32-51 and 55-71 is/are pending in the application.
- 4a) Of the above claim(s) \_\_\_\_\_ is/are withdrawn from consideration.
- 5) ☐ Claim(s) \_\_\_\_\_ is/are allowed.
- 6) ☒ Claim(s) 1-17, 20-28, 32-51, 55-71 is/are rejected.
- 7) ☐ Claim(s) \_\_\_\_\_ is/are objected to.
- 8) ☐ Claim(s) \_\_\_\_\_ are subject to restriction and/or election requirement.

### Application Papers

- 9) ☐ The specification is objected to by the Examiner.
- 10) ☐ The drawing(s) filed on \_\_\_\_\_ is/are: a) ☐ accepted or b) ☐ objected to by the Examiner.  
Applicant may not request that any objection to the drawing(s) be held in abeyance. See 37 CFR 1.85(a).  
Replacement drawing sheet(s) including the correction is required if the drawing(s) is objected to. See 37 CFR 1.121(d).
- 11) ☐ The oath or declaration is objected to by the Examiner. Note the attached Office Action or form PTO-152.

### Priority under 35 U.S.C. § 119

- 12) ☐ Acknowledgment is made of a claim for foreign priority under 35 U.S.C. § 119(a)-(d) or (f).
- a) ☐ All b) ☐ Some \* c) ☐ None of:
- ☐ Certified copies of the priority documents have been received.
  - ☐ Certified copies of the priority documents have been received in Application No. \_\_\_\_\_.
  - ☐ Copies of the certified copies of the priority documents have been received in this National Stage application from the International Bureau (PCT Rule 17.2(a)).

\* See the attached detailed Office action for a list of the certified copies not received.

### **DETAILED ACTION**

1. Claims 1-17, 20-28, 32-51, 55-71 have been considered. Claims 1, 4-5, 35, 37-47, 49-51, 67 and 70 amended as per Applicant's request.

### ***Claim Rejections - 35 USC § 102***

2. The following is a quotation of the appropriate paragraphs of 35 U.S.C. 102 that form the basis for the rejections under this section made in this Office action:

A person shall be entitled to a patent unless –

(b) the invention was patented or described in a printed publication in this or a foreign country or in public use or on sale in this country, more than one year prior to the date of application for patent in the United States.

3. Claims 17, 20-28 and 32 are rejected under 35 U.S.C. 102(b) as being anticipated by Lawlor et al. (USPN 5,485,626, herein Lawlor).

4. As per Claim 17, Lawlor teaches: An apparatus, comprising:  
execution resources to execute a plurality of instructions (Column 10, Lines 47 and 51, the processors),  
the execution resources to receive a non-privileged user instruction (Column 8, Lines 37-42. Furthermore, the disclosed invention is geared towards not using the operating system (Abstract and Column 6, Lines 38-42), meaning that these instructions would be non-privileged);  
the execution resources further to, responsive to the received instruction, execute a first shared resource thread ("shred") concurrently with at least a second shred (Column 12, Lines 31-32); and

a shared register to be addressable by a user-level instruction (Column 17, Line 13, the SRQ object. Column 8, Lines 59-60 show that the objects are stored in registers), the shared register to be directly accessible by at least the first shred and the second shred to provide communication between the first shred and the second shred (Column 19, Lines 31-32).

5. As per Claim 20, Lawlor teaches the apparatus of claim 18, wherein the shared register comprises a first register to enable an operating system or BIOS to enable multithreading architecture extensions for user-level multithreading (Column 18, Lines 13-19).

6. As per Claim 21, Lawlor teaches: The apparatus of claim 17, wherein the shared register comprises a first register to be atomically updated to synchronize data between the first and the second shred (Column 7, Line 62 – Column 8, Line 5).

7. As per Claim 22, Lawlor teaches: The apparatus of claim 17, wherein the execution resources include one or more processor cores capable of executing multiple shreds concurrently (Column 10, Lines 47 and 51).

8. As per Claim 23, Lawlor teaches: The apparatus of claim 17, wherein the shared register is to hold at least a portion of a state shared among the first shred and the second shred (Column 8, Lines 20-24, they share an object space containing counters

and queues, which can be implemented in registers as seen in Column 8, Lines 59-60).

9. As per Claim 24, Lawlor teaches: The apparatus of claim 17, wherein the first shred and the second shred share a current privilege level and share a common address translation (Column 8, Lines 37-42 show that the compiler creates instructions to create parallelism (threads/shreds) outside of the operating system, giving them the same privilege level (non privileged) as the others. In addition, Column 8, Lines 20-23 discusses the addressing).

10. As per Claim 25, Lawlor teaches: The apparatus of claim 17, further comprising logic to execute a user-level instruction to create the first shred (Column 8, Lines 37-42).

11. As per Claim 26, Lawlor teaches: The apparatus of claim 17, wherein the shared register comprises a first register to be utilized as a register semaphore to synchronize data between the first and the second shred (Column 12, Lines 42-46).

12. As per Claim 27, Lawlor teaches: The apparatus of claim 17, further comprising a group of register to share a system state among the first shred and the second shred (Column 8, Lines 20-28).

13. As per Claim 28, Lawlor teaches: The apparatus of claim 17, further comprising a group of registers, which does not include the shared register, to hold a private portion of a state to be associated with the first shred (Inherent in multithreaded systems, each thread uses general purpose (among other) registers, which defines their state. The very definition of a thread requires a private state. Column 7, Line 25 discloses that context switching occurs (although not for the reason mentioned in that paragraph), which is done in multithreading systems to save the private state of each thread when another thread needs to run on that processor).

14. As per Claim 32, Lawlor teaches: The apparatus of claim 17, further comprising:  
a user-level exception mechanism to report an exception to the first shred  
(Column 18, Lines 21-22).

***Claim Rejections - 35 USC § 103***

15. The following is a quotation of 35 U.S.C. 103(a) which forms the basis for all obviousness rejections set forth in this Office action:

(a) A patent may not be obtained though the invention is not identically disclosed or described as set forth in section 102 of this title, if the differences between the subject matter sought to be patented and the prior art are such that the subject matter as a whole would have been obvious at the time the invention was made to a person having ordinary skill in the art to which said subject matter pertains. Patentability shall not be negated by the manner in which the invention was made.

16. Claims 1-12 and 15 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor, in view of Galvin et al. (herein Galvin)

17. As per Claim 1, Lawlor teaches: A method, comprising:

encountering a non-privileged user-level programming instruction (Column 8, Lines 37-42. Furthermore, the disclosed invention is geared towards not using the operating system (see Column 4, Lines 20-24 and Abstract), meaning that these instructions would be non-privileged, as seen in the Foldoc articles “privileged instruction” and “supervisor mode”); ,

wherein creating the first shred is performed without the intervention of an operating system (Abstract and Column 6, Lines 38-42); and

executing, responsive to the programming instruction, the first shred concurrently with at least one of the one or more other shreds (Column 12, Lines 31-32);

wherein creating the first shred is performed in hardware, without the intervention of an operating system (Abstract and Column 6, Lines 38-42); but fails to teach:

creating, responsive to the programming instruction, a first shared resource thread (shred) that is associated with a first private portion of a first application state and shares a second shared portion of the first application state with at least a second shred

wherein the first application state is a private application state of a first thread.

While Lawlor teaches a method which has a first and second shred which are associated with an application state, Lawlor does not teach that this application state is a private application state of a first thread, nor does he teach that there is a private and shared portion of the application state. However, Galvin teaches that threads (the shreds of the claim) are implemented by being subdivisions of a process (the thread in the claim), and the threads utilize the address space and other resources of the process (Pages 111-115), but are can also be partitioned to have some of their own private

resources (Page 106). Given that when a process is operating independently, its state is private (to other processes, see Pages 108-109), any thread which is a part of a process which is independent is therefore associated with a private application state of the process, since the entire application state is private. Given that Galvin teaches the fundamentals of how threads work, and the advantages that are gained as a result of using processes and threads, one of ordinary skill in the art would have been motivated to use Galvins teachings to implement the threads in Lawlor.

18. As per Claim 2, Lawlor teaches: The method of claim 1, wherein the first private portion of an application state is associated with at least one of a plurality of registers including general purpose registers, floating point registers, MMX registers, segment registers, a flags register, an instruction pointer, control and status registers, SSE registers, and a MXCSR register (It is inherent that each thread of execution has these registers in their private state, or they cannot function as intended).

19. As per Claim 3, Lawlor teaches: The method of claim 1, but fails to teach:  
the first thread includes a first-operating-system-generated thread to execute a first process.

Lawlor teaches a first application state having private and shared portions, but does not teach that the state is associated with an operating system generated thread which executes a process. However, Galvin teaches about processors and threads, in that a process/task contains one or more threads to execute the functionality of the

process (see pages 111-115, and that this is the organization of how threads work (threads are part of a process/task, and that threads must be part of a process/task).

Galvin also teaches on page 112 that the advantage of having multiple threads operate in a single process is that if one thread blocks, the other threads can run, leading to higher throughput and improved performance. Given these two advantages, one of ordinary skill in the art would have been motivated to use the teachings of Galvin to utilize the threads in processes, as that is how they are required to be organized.

20. As per Claim 4, Galvin teaches: The method of claim 3, further comprising:

creating a second operating system generated thread to execute a second process in response to a privileged non-user level programming instruction, the second operating system generated thread to be associated with a second application state (Galvin, page 106, more than one process can be created); and

creating a third shred, in response to encountering a second non-privileged user-level programming instruction associated with the second process, wherein the third shred is to be associated with a shared portion and a private portion of the second application state (Galvin, Pages 111-112, each process has threads, so the thread/shred of Claim 1 would be made here too),

wherein the second operating system generated thread and the third shred do not share a portion of the first application state (Galvin, page 108, independent processes).

21. As per Claim 5, Lawlor teaches: The method of claim 1, wherein the first shred and the second shred share a current privilege level and share a common address translation (Column 8, Lines 37-42 show that the compiler creates instructions to create parallelism (threads/shreds) outside of the operating system, giving them the same privilege level (non privileged) as the others. In addition, Column 8, Lines 20-23 discusses the addressing).

22. As per Claim 6, Lawlor teaches: The method of claim 1, further comprising:  
receiving a non-privileged user-level programming instruction that encodes a shred destroy operation (Column 29, Lines 27, 49, and Column 30, Line 4).

23. As per Claim 7, Lawlor teaches: The method of claim 1, further comprising communicating between the first shred and the second shred (Column 17, Lines 13-18).

24. As per Claim 8, Lawlor teaches: The method of claim 1, further comprising sharing a system state among at least the first and second shreds (Column 8, Lines 20-28).

25. As per Claim 9, Lawlor teaches: The method of claim 7, wherein said communicating is performed via one or more shared registers (Column 19, Lines 31-32).

26. As per Claim 10, Lawlor teaches: The method of claim 1, further comprising:  
scheduling, responsive to a user-level programming instruction, the first shred  
and the second shred without intervention of the operating system (Column 7, Lines 37-  
42).
27. As per Claim 11, Lawlor teaches: The method of claim 7, wherein:  
said communicating is performed via a user-level shred signaling instruction  
(Column 17, Lines 13-18).
28. As per Claim 12, Lawlor teaches: The method of claim 11, further comprising:  
storing at least the first private portion of the first application state in a memory  
responsive to receipt of a context switch request (inherent in a context switch).
29. As per Claim 15, Lawlor teaches: The method of claim 1, wherein:  
the shred is to perform input/output (I/O) operations (Column 12, Lines 35-41).
30. As per Claim 16, Lawlor teaches: The method of claim 1, wherein:  
the one or more shreds are to perform computation functions (Column 12, Lines 31-32).
31. Claims 35-44, 50-51, and 62-65 are rejected under 35 U.S.C. 103(a) as being  
unpatentable over Lawlor and Galvin, further in view of Patterson et al. (herein  
Patterson).

32. As per Claim 35, Lawlor teaches: An article of manufacture, comprising:  
a machine-accessible medium including data that, when accessed by a machine, cause the machine to perform operations comprising,  
executing the plurality of user-level threads of execution concurrently on multiple instruction sequencers (Column 12, Lines 31-32), but fails to teach:  
executing the threads concurrently in a processor in the machine;  
receiving user-level programming instructions to execute a plurality of user-level threads of execution, wherein each of the plurality of user-level threads of execution are to be associated with a private state of an OS-generated thread and to share a system state with the OS-generated thread.

Lawlor teaches user-level instructions to execute a plurality of threads, however, Lawlor is silent towards the threads being associated with a private state and sharing a system state with an OS-generated thread, although Lawlor does teach of operating systems which support threading. However, Galvin teaches about processes and threads, and that a process (or task) is created by the operating system, and that threads are spawned for each process, with their own private states, but also share a common state (the address space of the process, see Pages 111-115), and these processes are created by the operating system (Page 106). Additionally, when a process creates a thread, it may partition its resources to each thread, thus there could be "private states" of the process (the partitioned resources) associated with each user-level thread (Page 106). Given that a process is essentially a thread, one could consider

a process/task to be an operating-system generated thread, and given the need to know how to implement an OS with threading, without Lawlor providing the specifics and high-level implementation, one of ordinary skill in the art would have been motivated to combine the teachings of Galvin into Lawlor's invention in order to see how to use an OS with the invention properly, and would have incorporated the knowledge of processes into the invention (which are also extremely well known in the art of multithreading), thus the user-level threads created by Lawlor would share a state with the process upon which they are created from.

Furthermore, Lawlor teaches that multiple processors can run multiple threads concurrently, however, does not teach that a single processor can execute multiple threads concurrently. However, the idea of executing multiple threads on a single processor is extremely well known in the art, as illustrated by the textbook teachings of Patterson, which disclose Simultaneous Multi-Threading (herein SMT), along with its numerous advantages, for example, increased throughput (see Pages 611-612). Given this advantage, one of ordinary skill in the art at the time the invention was made would have been motivated to have each processor in Lawlor execute multiple threads at the same time, to even further increase the throughput of the system.

33. As per Claim 36, Lawlor teaches: The article of manufacture of claim 35, wherein the operations further comprise:

the private state is associated with at least one of a plurality of registers including general purpose registers, floating point registers, MMX registers, segment registers, a

Art Unit: 2183

flags register, an instruction pointer, control and status registers, SSE registers, and a MXCSR register (Column 18, Lines 14-18).

34. As per Claim 37, Lawlor teaches: The article of manufacture of claim 35, wherein the private state includes a private portion of an application state (inherent), and wherein the plurality of user-level threads of execution are also to share a shared portion of the application state, the shared portion of the application state to be associated with at least one of a plurality of registers including a control register, a flags register, memory management registers, a local descriptor table register, a task register, debug registers, model specific registers, shared registers, and shared control registers (Column 11, Lines 3-5 show the program context is stored in the SV register 112).

35. As per Claim 38, Lawlor teaches: The article of manufacture of claim 35, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising:

sharing a state among the plurality of user-level threads of execution; and storing the state in one or more registers (Column 8, Lines 20-24, they share an object space containing counters and queues, which can be implemented in registers as seen in Column 8, Lines 59-60).

36. As per Claim 39, Lawlor teaches: The article of manufacture of claim 35, wherein the plurality of user-level threads of execution share a current privilege level and share a common address translation (Column 8, Lines 37-42 show that the compiler creates instructions to create parallelism (threads/shreds) outside of the operating system, giving them the same privilege level (non privileged) as the others. In addition, Column 8, Lines 20-23 discusses the addressing).

37. As per Claim 40, Lawlor teaches: The article of manufacture of claim 35, wherein the user-level programming instructions include an instruction to create one or more of the plurality of user-level threads of execution (Column 8, Lines 37-42).

38. As per Claim 41, Lawlor teaches: The article of manufacture of claim 35, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising communicating among the plurality of user-level threads of execution (Column 17, Lines 13-18).

39. As per Claim 42, Lawlor teaches: The article of manufacture of claim 35, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising sharing a system state among the plurality of user-level threads of execution (Column 8, Lines 20-28).

40. As per Claim 43, Lawlor teaches: The article of manufacture of claim 35, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising communicating between the plurality of user-level threads of execution via one or more shared registers (Column 19, Lines 31-32).

41. As per Claim 44, Lawlor teaches: The article of manufacture of claim 35, wherein an application program controls the plurality of user-level threads of execution directly, including scheduling of the plurality of user-level threads of execution, and wherein an operating system executed by the multiprocessor schedules the OS-generated thread (Column 2, Lines 21-31).

42. As per Claim 50, Lawlor teaches: The article of manufacture of claim 35, wherein the plurality of user-level threads of execution perform input/output (I/O) functions and computation functions (Column 12, Lines 31-41).

43. As per Claim 51, Lawlor teaches: A system, comprising:  
a microprocessor implementing an instruction set architecture (ISA) (Column 7, Lines 1-4); and  
a memory to store one or more instructions of the ISA (Figure 2, Memory 211 and cache 201) that is to allow user-level multithreading operations (Column 7, Lines 1-4), but fails to teach:

the microprocessor capable of executing multiple OS-generated threads, wherein the microprocessor is also capable of concurrently executing multiple shared resource threads (shreds) associated with one of the OS-generated threads, wherein each of the multiple shreds are associated with a private state within the OS-generated thread and a shared state of the OS-generated thread.

Lawlor teaches user-level instructions to execute a plurality of threads, however, Lawlor is silent towards the threads being associated with a private state and sharing a system state with an OS-generated thread, although Lawlor does teach of operating systems which support threading. However, Galvin teaches about processes and threads, and that a process (or task) is created by the operating system, and that threads are spawned for each process, with their own private states, but also share a common state (the address space of the process, see Pages 111-115), and these processes are created by the operating system (Page 106). Additionally, when a process creates a thread, it may partition its resources to each thread, thus there could be "private states" of the process (the partitioned resources) associated with each user-level thread (Page 106). Given that a process is essentially a thread, one could consider a process/task to be an operating-system generated thread, and given the need to know how to implement an OS with threading, without Lawlor providing the specifics and high-level implementation, one of ordinary skill in the art would have been motivated to combine the teachings of Galvin into Lawlor's invention in order to see how to use an OS with the invention properly, and would have incorporated the knowledge of processes into the invention (which are also extremely well known in the art of

multithreading), thus the user-level threads created by Lawlor would share a state with the process upon which they are created from.

Furthermore, Lawlor teaches that multiple processors can run multiple threads concurrently, however, does not teach that a single processor can execute multiple threads concurrently. However, the idea of executing multiple threads on a single processor is extremely well known in the art, as illustrated by the textbook teachings of Patterson, which disclose Simultaneous Multi-Threading (herein SMT), along with its numerous advantages, for example, increased throughput (see Pages 611-612). Given this advantage, one of ordinary skill in the art at the time the invention was made would have been motivated to have each processor in Lawlor execute multiple threads at the same time, to even further increase the throughput of the system.

44. As per Claim 62, Lawlor teaches: The article of manufacture of claim 35, wherein the one or more user-level programming instructions include an instruction to destroy one or more of the plurality of shreds (Column 29, Lines 27, 49, and Column 30, Line 4).

45. As per Claim 63, Lawlor teaches: The system of claim 51, wherein the one or more instructions include an instruction to create a shred without intervention of an operating system (Column 4, Lines 20-23).

46. As per Claim 64, Lawlor teaches: The system of claim 51, wherein the one or more instructions include an instruction to destroy a shred without intervention of an

operating system (Column 29, Lines 27, 49, and Column 30, Line 4).

47. As per Claim 65, Lawlor teaches: The system of claim 51, wherein: the user-level multi-threading operations include concurrent execution of two or more shreds associated with the same thread (Column 4, Lines 10-15, where it says that a shred (fork) is created when a part of the program is found to be able to be executed in parallel, thus all the shreds are threads of an overall process (the thread in this case)).

48. Claims 45-46 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor and Galvin, further in view of Foldoc.

49. As per Claim 45, Lawlor teaches: The article of manufacture of claim 35, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising:

associating the plurality of user-level threads of execution with the OS-generated thread (Column 8, Lines 20-24), but fails to teach:

suspending the plurality of user-level threads of execution belonging to the OS-generated thread when a context switch request is received through a single one of the plurality of threads of execution. In Column 18, Lines 13-18, Lawlor teaches that the context is saved when a thread goes inactive, but does not teach that all threads/shreds of a process would be made to be suspended on a context switch. However, Foldoc (Context switch) teaches that on a context switch between processes, the entire

process stops running, and another begins. Given that the reason to multithread is to maximize the shared state as much as possible, it would have been obvious to one of ordinary skill in the art at the time the invention was made to shut down all the shreds associated with the thread/process when it was switched out, so the new process could make use of the advantages of parallelism without the other shreds getting in the way.

50. As per Claim 46, Lawlor teaches: The article of manufacture of claim 45, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising:

storing one or more threads of execution states associated with the plurality of user-level threads of execution when the context switch request is received (Column 18, Lines 13-18).

51. Claims 13-14 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor and Foldoc, further in view of Golliver et al. (USPN 6,378,067, herein Golliver).

52. As per Claim 13, Lawlor teaches the method of claim 1, but fails to teach:

handling with user-level exception handler code an exception generated during execution of the first shred, without intervention of the operating system.

Lawlor teaches that exceptions can be generated and are dealt with (Column 18, Lines 21-22 for example), but does not explicitly disclose how this occurs, or what deals with the exceptions. Golliver teaches a method to handle multiple exceptions at once by

prioritizing them, and dealing with them in a non-operating system exception handler (Column 3, Line 66 – Column 4, Line 6, and Column 4, Lines 22-25. The operating system is not used to process the exception unless explicitly called, as shown in Column 7, Lines 22-27). Given the need for a method to handle exceptions, and the desire to minimize the operating systems involvement in thread processing in Lawlor's invention, and additionally the need to handle multiple exceptions which could come up when executing multiple shreds concurrently, it would have been obvious to one of ordinary skill in the art at the time the invention was made to use Golliver's exception handler to handle Lawlor's exceptions.

53. As per Claim 14, Golliver teaches: The method of claim 13, further comprising: receiving the exception from an application program (Column 4, Lines 22-26); and  
determining whether to report the exception to the operating system (Column 7, Lines 25-27).

54. Claims 33-34 and 59-61 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor, in view of Golliver.

55. As per Claim 33, Lawlor teaches the apparatus of claim 17, but fails to teach: an exception mechanism to report an exception to an operating system.

Lawlor teaches that exceptions can be generated and are dealt with (Column 18, Lines 21-22 for example), but does not explicitly disclose how this occurs, or what deals with the exceptions. Golliver teaches a method to handle multiple exceptions at once by prioritizing them, and dealing with them in a non-operating system exception handler (Column 3, Line 66 – Column 4, Line 6, and Column 4, Lines 22-25. The operating system is not used to process the exception unless explicitly called, as shown in Column 7, Lines 22-27). Given the need for a method to handle exceptions, and the desire to minimize the operating systems involvement in thread processing in Lawlor's invention (but still be able to use it when necessary), and additionally the need to handle multiple exceptions which could come up when executing multiple shreds concurrently, it would have been obvious to one of ordinary skill in the art at the time the invention was made to use Golliver's exception handler to handle Lawlor's exceptions.

56. As per Claim 34, Golliver teaches: The apparatus of claim 32, further comprising:  
a mechanism to a first exception associated with the first shred and a second exception associated with the second shred (Column 3, Line 66 – Column 4, Line 6, and Column 5, Lines 29-31);

wherein the exception mechanism includes a prioritizer to prioritize the first and the second exceptions (Column 4, Line 1); and

wherein the exception mechanism is further to report only one of the prioritized first and second exceptions at a time to the operating system (Column 7, Lines 23-28

disclose the operating system may be able to be told to handle exceptions, and Column 7, Lines 11-13 show that the faults can be reported one at a time).

57. As per Claim 59, Golliver teaches: The apparatus of claim 32, wherein: the user-level exception mechanism is further to vector to a fixed location in order to allow the shred to service to the exception (Figure 4, and Column 7, Lines 23-28, the user handler set).

58. As per Claim 60, Golliver teaches: The apparatus of claim 32, wherein: the plurality of instructions further include a system call instruction to explicitly invoke an operating system to service to the exception (Column 7, Lines 23-28).

59. As per Claim 61, Golliver teaches: The apparatus of claim 34, wherein said prioritizer employs a round-robin scheme (Column 7, Lines 11-12 and Column 5, Lines 30-32).

60. Claims 47-49 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor and Galvin, further in view of Golliver.

61. As per Claim 47, Lawlor teaches the article of manufacture of claim 35, but fails to teach:

wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising:

reporting one or more exceptions to a first thread of the plurality of user-level threads of execution.

Lawlor teaches exceptions occurring (Column 18 Lines 20-21 for example), but does not teach explicitly what happens during an exception. Golliver teaches a method to handle multiple exceptions at once by prioritizing them, and reporting them to a non-operating system exception handler (Column 3, Line 66 – Column 4, Line 6, and Column 4, Lines 22-25. The operating system is not used to process the exception unless explicitly called, as shown in Column 7, Lines 22-27). Given the need for a method to handle exceptions, and the desire to minimize the operating systems involvement in thread processing in Lawlor's invention (but still be able to use it when necessary), and additionally the need to handle multiple exceptions which could come up when executing multiple shreds concurrently, it would have been obvious to one of ordinary skill in the art at the time the invention was made to use Golliver's exception handler to handle Lawlor's exceptions.

62. As per Claim 48, Golliver teaches: The article of manufacture of claim 47, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising:

reporting the one or more exceptions from an application program (Column 2, Lines 42-47); and

determining whether to report the one or more exceptions to an operating system (Column 7, Lines 23-27).

63. As per Claim 49, Golliver teaches: The article of manufacture of claim 48, wherein the machine-accessible medium further includes data that causes the machine to perform operations comprising:

prioritized-reporting of the one or more exceptions to the operating system; comprising receiving the one or more exceptions concurrently via different user-level threads of the plurality of user-level threads of execution (Column 5, Lines 30-32); and servicing one of the one or more exceptions according to the prioritized-reporting while suspending exception processing of other exceptions of the one or more exceptions (Column 7, Lines 11-13).

64. Claims 55-58 and 66 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor, in view of Patterson.

65. As per Claim 55, Lawlor teaches: A system, comprising:

a microprocessor (Column 10, Line 58, Processor 106), including a plurality of user-level multithreading registers wherein the registers are addressable by one or more user-level instructions in each of a plurality of user-level threads and are to support communication among the user-level threads (Column 19, Lines 31-32); and

memory coupled to the microprocessor, the memory to store the one or more user-level instructions (Column 11, Lines 44-46), but fails to teach:

wherein the microprocessor is further to execute the user-level threads concurrently.

Lawlor teaches a multiprocessor system where each processor can work on a single thread/shred at a time, but does not teach that each individual processor is capable of executing more than one thread/shred at a time. However, the idea of executing multiple threads on a single processor is extremely well known in the art, as illustrated by the textbook teachings of Patterson, which disclose Simultaneous Multi-Threading (herein SMT), along with its numerous advantages, for example, increased throughput (see Pages 611-612). Given this advantage, one of ordinary skill in the art at the time the invention was made would have been motivated to have each processor in Lawlor execute multiple threads at the same time, to even further increase the throughput of the system.

66. As per Claim 56, Lawlor teaches: The system of claim 55, wherein the plurality of user-level multithreading registers further comprises a plurality of shared shred registers to facilitate communication between a plurality of shreds and to facilitate synchronization between the plurality of shreds (Column 19, Lines 31-32).

67. As per Claim 57, Lawlor teaches: The system of claim 56, wherein the plurality of user-level multithreading registers further comprises a plurality of shred control registers to manage the plurality of shreds (Column 18, Lines 13-18).

68. As per Claim 58, Lawlor teaches The system of claim 57, wherein the microprocessor:

receives programming instructions to execute one or more shreds in accordance with the ISA (Column 8, Lines 37-42);

configures one or more instruction sequencers via the ISA (Column 11, Lines 40-42); and

executes the one or more shreds concurrently (Column 12, Lines 31-32).

69. As per Claim 66, Lawlor teaches: The system of Claim 55, wherein the memory is from a plurality of memory devices including DRAM, flash, and EEPROM (Column 11, Lines 44-46).

70. Claims 67-71 are rejected under 35 U.S.C. 103(a) as being unpatentable over Lawlor, further in view of Galvin.

71. As per Claim 67, Lawlor teaches: An apparatus, comprising:  
a processor capable of user-level multithreading including:

a first group of resources to hold a per shared resource thread ("shred") application state for a first shred to be created by a first user-level instruction (Inherent in multithreaded systems, each thread uses general purpose (among other) registers, which defines their state. The very definition of a thread requires a private state. Column 7, Line 25 discloses that context switching occurs (although not for the reason mentioned in that paragraph), which is done in multithreading systems to save the private state of each thread when another thread needs to run on that processor);

a second group of resources, which is to include a replicate of the first group of resources, to hold a per shred application state for a second shred to be created by a second user-level instruction (Inherent in multithreaded systems, each thread uses general purpose (among other) registers, which defines their state. The very definition of a thread requires a private state. Column 7, Line 25 discloses that context switching occurs (although not for the reason mentioned in that paragraph), which is done in multithreading systems to save the private state of each thread when another thread needs to run on that processor); and

execution resources to concurrently execute the first shred and the second shred (Column 8, Lines 50-56), but fails to teach:

a second group of resources, which is to include a replicate of the first group of resources,

a third group of resources to be shared by the first shred and the second shred to hold a shared application state, the shared application state to be shared by a privileged-level software entity created thread; and

wherein the first, second, and third group of resources are private from another privileged-level software entity created thread.

Lawlor does not teach that the threads being executed concurrently share application state with a privileged-level software entity created thread (but does teach that threads can share object space, when the address spaces are shared). Galvin teaches about processes and threads, in that a process/task contains one or more threads to execute the functionality of the process (see pages 111-115), and that this is the organization of how threads work (threads are part of a process/task, and that threads must be part of a process/task). Galvin also teaches on page 112 that the advantage of having multiple threads operate in a single process is that if one thread blocks, the other threads can run, leading to higher throughput and improved performance. Given these two advantages, one of ordinary skill in the art would have been motivated to use the teachings of Galvin to utilize the threads disclosed in Lawlor to parallelize processes, where multiple threads reside in the same process (where all threads in a process share address space).

As a result of this application state being shared, it can also be seen that the second group of resources includes a replicate of the first group of resources, for example, see Page 111 of Galvin, which teaches that the threads for a process share the code section, data section, and operating system resources, thus each thread, which shares these resources, are replicated in every other thread.

Lawlor further does not teach that the first, second, and third group of resources are private from another privileged-level software entity created thread, however, Galvin

teaches on Pages 108-109 that processes can be either independent or cooperating, and independent threads do not share any data with any other processes, therefore, an independent processor would not allow any other process to have access to its (and as a result, its threads) resources.

72. As per Claim 68, Lawlor teaches: The processor of Claim 67, wherein:

the first group of resources, the second group of resources, and the third group of resources include registers (Column 8, Lines 59-60, also see other rejections on why the first and second groups (the private ones) contain registers), and wherein the first user-level instruction and the second user-level instruction are an Instruction Set Architecture instructions to create a shred, which are to be associated with a first user software entity and a second user software entity, respectively (Column 4, Lines 5-9).

73. As per Claim 69, Lawlor teaches: The apparatus of Claim 68, further comprising a hardware re-namer to allocate the first group of registers as private registers and the third group of registers as shared registers based on a bit vector (Column 8, Lines 19-24, the shared registers are determined by the object space, which is specified by the address space, which must be defined as a bit vector. Registers which aren't shared are private).

74. As per Claim 70, Galvin teaches: The apparatus of Claim 67, wherein the application state to be shared by the privileged-level software entity thread is not shared

with other privileged-level software entity threads, and wherein the privileged level software entity is an operating system (OS) (Pages 108-109, independent processes).

75. As per Claim 71, Lawlor and Galvin teaches: The apparatus of Claim 67, wherein the second group of resources is a copy of the first group of resources, and wherein the first group of resources includes a combination of resources selected from a group consisting of general registers, floating point registers, SSE registers, instruction pointer, and flags (Galvin, Page 111), and wherein the third group of resources includes a combination of resources selected from a group consisting of general registers, floating point registers, shared communication registers, flags, memory management registers, address translation tables, privilege levels, and control registers (Column 17, Lines 13-19).

### ***Response to Arguments***

1. Applicants arguments in regard to Claim 1 have been considered, but are moot in light of the new grounds of rejection for the claim.
2. Regarding Applicants arguments towards Claim 17 and Claim 55 (which is rejected under a different ground, but for almost identical reasons), Applicant has argued that Lawlor does not teach the limitation of the shared register being "addressable by a user-level instruction". Applicant has pointed out how Lawlor teaches that a user cannot access (object storage) directly at any time. However, Examiner sees

a user-level instruction to be a non-privileged instruction, such as is implied in the second line of the claim. While a user may not be able to write and execute an instruction to directly address and access the register, the send and receive instructions used by Lawlor are still user-level instructions, because they are not privileged (kernel/OS) instructions. Examiner believes that this is an important and distinct difference, and as a result, believes that Lawlor appropriately rejects the claim, because while the Examiner admits that a user cannot write and execute an instruction to directly access the object storage in Lawlor, that is not what a user-level instruction is, at least according to the Examiners interpretation. Examiner has looked to the Applicants specification for clarification, and noted in Paragraph 17, that user-level can be directed towards non-privileged code or application programs, distinguished from operating system code or privileged software. While Examiner also notes that in Column 11, Lawlor says that an application program does not have access to object storage, Examiner does not believe this necessarily implies that only privileged software can access object storage, as there is no indication that the token processors or PE units are only used in privileged mode. While in one interpretation given by the specification, user-level can mean application programs, it can also mean non-privileged code, and in that interpretation, the claim is taught by Lawlor.

If the claim said, for example, a shared register to be directly addressable by a user in an instruction, or addressable by an application program instruction, or something similar, that would potentially change things, but that is not what the claim says at present.

Applicant has further argued that the SRQ is a queue, and is used to indirectly pass information from thread to thread, thus the register is not directly accessible for each thread. However, the SRQ is stored in a register, and both threads can directly access the SRQ, thus they must both be able to directly access the register in which the SRQ is stored in.

3. Regarding Applicants arguments for Claims 35 and 51, Applicant has argued that Lawlor does not teach a plurality of private states (associated with user-level threads) with a thread (such as an OS generated thread, referred to here as a process for clarities sake), but rather only be inference that threads themselves have a private state from other threads. Firstly, Examiner notes that on Page 111 on Galvin, for example, it is noted that in the very least, each thread has its own individual program counter, so in the very least, that is a private state from other threads. However, in Page 106 of Galvin, it is taught that each process, when creating threads, may partition its resources for each thread, which is distinguished from it sharing those resources with other threads, therefore, those resources can be considered a private state of the process to which each thread is associated with.

4. Regarding Applicants arguments for Claim 67, Applicant has argued that the references do not teach each thread having private replicated resources, to hold private information. However, Examiner does not read the claim in the same way that the Applicant does, Examiner reads the claim that the second group of resources includes

resources (which could be a subset of the resources) which are a "replicate" of the first group of resources (Although Examiner is not entirely sure what the Applicant means by a replicate), and notes that in Galvin, it is shown that several resources for each thread are shared between all threads, thus those shared resources are identical in each thread, appearing to be a "replicate" from Examiners best understanding of the term. The only other interpretation Examiner can think of for what the Applicant is attempting to claim is that each thread has similar hardware, IE, the same number of registers, memory space, etc, and Examiner believes that that would be an obvious design choice when making threads, since Galvin says that the process partitions resources among its threads, and Examiner believes that it would have been obvious to one of ordinary skill in the art to make that partitioning of resources equal among the threads.

### ***Conclusion***

5. Applicant's amendment necessitated the new ground(s) of rejection presented in this Office action. Accordingly, **THIS ACTION IS MADE FINAL**. See MPEP § 706.07(a). Applicant is reminded of the extension of time policy as set forth in 37 CFR 1.136(a).

A shortened statutory period for reply to this final action is set to expire THREE MONTHS from the mailing date of this action. In the event a first reply is filed within TWO MONTHS of the mailing date of this final action and the advisory action is not mailed until after the end of the THREE-MONTH shortened statutory period, then the shortened statutory period will expire on the date the advisory action is mailed, and any

extension fee pursuant to 37 CFR 1.136(a) will be calculated from the mailing date of the advisory action. In no event, however, will the statutory period for reply expire later than SIX MONTHS from the date of this final action.

Any inquiry concerning this communication or earlier communications from the examiner should be directed to ROBERT E. FENNEMA whose telephone number is (571)272-2748. The examiner can normally be reached on Monday-Friday, 8:30-6:00.

If attempts to reach the examiner by telephone are unsuccessful, the examiner's supervisor, Eddie Chan can be reached on (571) 272-4162. The fax phone number for the organization where this application or proceeding is assigned is 571-273-8300.
